

Product Card

Your name: Vega

Product name: Ecomvox

Reminder: Do not use AI to fill in this card. AI can be a thought partner to brainstorm, but the words should be your own.

1. Problem Statement

Write the problem statement. Be as specific as possible — the more specific you are, the clearer your product will be. Format: [User] struggles with [specific pain point] because [root cause], which means [consequence].

An E-commerce Analyst struggles with stale performance reporting and delayed decision-making regarding inventory and ad spend because multi-platform sales, inventory, and marketing data are not automatically unified at the ingestion layer, which means the brand wastes ad budget on underperforming campaigns, suffers preventable stockouts on top SKUs, and loses high-margin revenue.

2. Solution Description

In 2-3 sentences, describe what your product does and how it solves the problem. Write this for a non-technical audience -- no code, no jargon. Just: what does the product do, who does it help, and what changes for them.

Navi Pivot automatically connects store inventory with ad campaign spend to give e-commerce analysts real-time visibility into product profitability. It alerts team members when ad campaigns are actively driving paid traffic to out-of-stock items and highlights top-selling products that need immediate inventory reorders. This stops brands from wasting ad budget on products they cannot fulfill and protects high-margin revenue from preventable stockouts.

3. MVP User Flow

List the steps a user takes through your product from start to finish. Every step should be necessary -- if removing it doesn't break the product, it probably doesn't belong here yet. Aim for 4 to 6 steps.

Step	What happens
1	User connects their Shopify store and Meta Ads account.
2	User sets inventory and performance alert rules (e.g., flag ads when SKU stock drops below 10 units).
3	System matches backend store inventory with live ad campaigns by SKU ID.
4	User views the dashboard displaying real-time campaign profitability and actionable alerts.

Section 1: Problem Statement "An E-commerce Analyst struggles with stale performance reporting and delayed decision-making regarding inventory and ad spend because multi-platform sales, inventory, and marketing data are not automatically unified at the ingestion layer, which means the brand wastes ad budget on underperforming campaigns, suffers preventable stockouts on top SKUs, and loses high-margin revenue."

Section 2: Solution Description "Navi Pivot automatically connects online store inventory with ad campaign spend to give e-commerce analysts real-time visibility into product profitability. It alerts team members when ad campaigns are actively driving paid traffic to out-of-stock items and highlights top-selling products that need immediate inventory reorders. This stops brands from wasting ad budget on products they cannot fulfill and protects high-margin revenue from preventable stockouts."

Section 3: MVP User Flow User connects store and ad accounts: The analyst links their Shopify store and Meta Ads manager. User sets threshold rules: The analyst establishes simple logic triggers (e.g., flag campaigns when target SKU inventory drops below 10 units). System unifies data: The platform automatically matches backend store inventory with active ad campaigns by SKU ID. User reviews dashboard: The analyst views real-time profitability metrics alongside automated, high-priority alerts. User executes action: The analyst triggers the recommended fix—either pausing wasted ad spend or initiating a reorder—directly from the interface.

Partner Feedback:

My partner pointed out that in Step 2 (Set alert rules), an analyst might not always know what inventory threshold to set manually for every single SKU off the top of their head, especially if they have hundreds of products with different sales velocities. They suggested having preset or auto-recommended threshold defaults based on recent burn rate.

Specific Change Made:

I tightened Step 2 so that instead of requiring the user to build threshold rules from scratch, the system pre-populates smart default rule templates (e.g., "Alert when SKU inventory drops below 5 days of average sales volume"). The user simply toggles or adjusts these smart defaults on onboarding, reducing setup friction while keeping full manual control if they want it.
